Introduction

Motivation and Question

What is the quantitative impact of **used capital market** in recessions?

- Khan and Thomas (2013) shows that **credit shocks** are an important factor for replicating the Great Recession dynamics.
- Lanteri and Rampini (2023) characterizes two capital market inefficiencies:
 - ① price-dependent collateral constraints **endogenously tightened**,
 - ② **cheaper** price **facilitates** real sector production, offsets credit shock.
- What are the dynamic implications of these inefficiencies in a Khan and Thomas (2013) economy?

Model

Overview

I consider a **heterogeneous firm model** with **real and financial friction**:

- **Used investment market**: trade price q is determined by the supply (downward-adjust) and the demand (upward-adjust) Def
- **Households**: own firms \Rightarrow firms discount as HH. HH Problem
- **Firms**: idio.: ϵ_i ; exogenous exit prob π_d ; TFP: z ; credit ζ
 - Upward-adjusting firms: purchase **effective capital** at cost Q .
 - LoM: $CES(i_{used}, i_{new}) \Rightarrow K$
 - implies optimal i_{used}/i_{new} ratio CES cost minimization problem
 - Downward-adjusting firms: sells **used investment goods** at price q .
 - Collateral constraint: $b' \leq q\zeta k$.

Production and Value Function

- Firms experience exogenous exit π_d :

$$v_0(k, b, \varepsilon; \mathbf{s}_f, \mu) = \pi_d \max_n [x^d(k, b, \varepsilon; \mathbf{s}_f)] + (1 - \pi_d)v(k, b, \varepsilon; \mathbf{s}_f, \mu),$$

- Conditional on survival, firm chooses upward- or downward-adjusting:

$$v(k, b, \varepsilon; \mathbf{s}_f, \mu) = \max\{v^u(k, b, \varepsilon; \mathbf{s}_f, \mu), v^d(k, b, \varepsilon; \mathbf{s}_f, \mu)\}.$$

- capital process for upward-adjusting firms (Lanteri (2018)):

$$k' = (1 - \delta)k + \left[\eta^{\frac{1}{s}} (i_{new})^{\frac{s-1}{s}} + (1 - \eta)^{\frac{1}{s}} (i_{used})^{\frac{s-1}{s}} \right]^{\frac{s}{s-1}},$$

leads to $\frac{i_{used}}{i_{new}} = \frac{1-\eta}{\eta} (q + \gamma)^{-s}$, and $Q = [\eta + (1 - \eta)(q + \gamma)^{1-s}]^{\frac{1}{1-s}}$

- capital process for downward-adjusting firms: $k' = (1 - \delta)k - d$.

Upward-adjusting Firm

$$v^u(k, b, \varepsilon; \mathbf{s}_f; \mu) = \max_{\mathbf{k}', \mathbf{b}', D} D + \sum_{g=1}^{N_s} \pi_{fg}^{\mathbf{s}} d_g(\mathbf{s}_f; \mu) \sum_{j=1}^{N_\varepsilon} \pi_{ij}^{\varepsilon} v_0(k', b', \varepsilon'_j; \mathbf{s}'_g; \mu'),$$

subject to

$$0 \leq D \leq \mathbf{x}^u(k, b, \varepsilon_i; z_f) + q_b b' - Q k', \quad (\text{Budget: Up})$$

$$\mathbf{x}^u(k, b, \varepsilon_i; z_f) = z_f \epsilon_i F(k, n) - w(z_f, \mu) n - b + Q(1 - \delta)k \quad (\text{Cash: Up})$$

$$b' \leq q \zeta k, \quad (\text{Collateral})$$

$$k' \geq (1 - \delta)k, \quad (\text{K range})$$

$$\mu' = \Gamma(z_f; \mu), \quad (\text{Distribution})$$

q_b : bond price; $d_g(z_f, \mu)$: SDF; ζ : efficiency of financial sector.

Downward-adjusting Firm [Back](#)

$$v^d(k, b, \varepsilon_i; \mathbf{s}_f, \mu) = \max_{k', b', D} D + \sum_{g=1}^{N_s} \pi_{fg}^{\mathbf{s}} d_g(\mathbf{s}_f; \mu) \sum_{j=1}^{N_\varepsilon} \pi_{ij}^{\varepsilon} v_0(k', b', \varepsilon'_j; z'_g, \mu'),$$

subject to

$$0 \leq D \leq x^d(k, b, \varepsilon; z_f) + q_b b' - q k', \quad (\text{Budget: Down})$$

$$x^d(k, b, \varepsilon; z_f) = z_f \epsilon_i F(k, n) - w(z_f, \mu) n - b + q(1 - \delta)k \quad (\text{Cash: Down})$$

$$b' \leq q \zeta k, \quad (\text{Collateral})$$

$$k' \leq (1 - \delta)k, \quad (\text{K range})$$

$$\mu' = \Gamma(z_f; \mu), \quad (\text{Distribution})$$

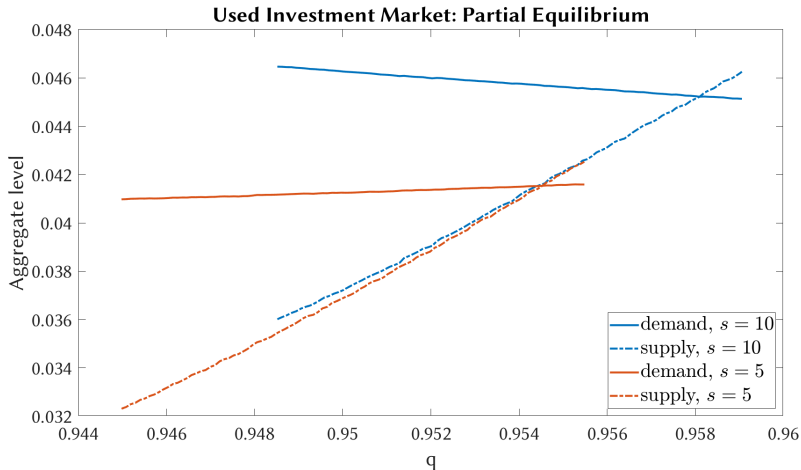

Definition of recursive equilibrium, Rewrite in terms of $p(z_f; \mu)$

Steady State Calibration

parameter	target		model
$\beta = 0.96$	real rate	$= 0.040$	0.040

Used capital prices q increases with negative credit shocks

Evaluating the effect on time-varying collateral constraint

TFP shock expandCredit shock expand

effect on time-varying collateral constraint is very small

Brief Discussion

- Recall two channels: why does time-varying collateral constraint have little effect?
 - every firm invests in the same i_{new}/i_{used} ratio
 - \Rightarrow young firms hold the same percentage of old capital as old firms.
 - \Rightarrow bans interaction between bond and i_{used}
- Cheaper used K prices do facilitate production at a cost of consumers
 - response in baseline model is weaker, except drop in consumption
 - consumer as the funding source: less resource for consumption
 - the role of used capital: decrease the cost of capital accumulation

Next Steps

- ① Having a “real” old capital? What's the difference b/w new and old?
 - Lanteri and Rampini (2023): collateral externality v.s. distributive externality in steady state
- ② What is the role of old capital in supply chain disruption?
 - Darmouni and Sutherland (2023): old firms price out young firm for old capital
- ③ Does collateral constraints matter for large firms?
 - Lian and Ma (2020): the anatomy of borrowing constraints in US.
 - small firms borrow 20% of total debt through collateral;
 - large firms borrow 80% of total debt through earning-based.
- ④ Firm dynamics: how will price change with endo. entry & exit?

CES Cost Minimization Problem I

[Back](#)

The CES cost minimization problem to at least achieve \bar{I} level of investment is given by

$$\begin{aligned} \min_{i_{new}, i_{used}} \quad & i_{new} + (q + \gamma)i_{used} \\ \text{s.t.} \quad & \left[\eta^{\frac{1}{s}} (i_{new})^{\frac{s-1}{s}} + (1 - \eta)^{\frac{1}{s}} (i_{used})^{\frac{s-1}{s}} \right]^{\frac{s}{s-1}} \geq \bar{I}. \end{aligned} \quad (1)$$

Note that constraint must bind, so we can denote

$$\bar{I}^{\frac{s-1}{s}} = \left[\eta^{\frac{1}{s}} (i_{new})^{\frac{s-1}{s}} + (1 - \eta)^{\frac{1}{s}} (i_{used})^{\frac{s-1}{s}} \right]. \quad (2)$$

CES Cost Minimization Problem II

[Back](#)

Let the Lagrangian multiplier be λ , the FOC w.r.t. i_{new} and i_{used} are

$$\begin{aligned} [i_{new}] : \quad 1 &= \lambda \eta^{\frac{1}{s}} i_{new}^{-\frac{1}{s}} \bar{I}^{\frac{1}{s}} \\ [i_{used}] : \quad q + \gamma &= \lambda (1 - \eta)^{\frac{1}{s}} i_{used}^{-\frac{1}{s}} \bar{I}^{\frac{1}{s}}, \end{aligned} \tag{3}$$

Rearrange (3) w.r.t. investment,

$$\begin{aligned} i_{new} &= \eta \bar{I} \left(\frac{1}{\lambda} \right)^{-s} \\ i_{used} &= (1 - \eta) \bar{I} \left(\frac{q + \gamma}{\lambda} \right)^{-s}. \end{aligned} \tag{4}$$

Divide and we get

$$\frac{i_{used}}{i_{new}} = \frac{1 - \eta}{\eta} (q + \gamma)^{-s}. \tag{5}$$

CES Cost Minimization Problem III

[Back](#)

Substitute (4) back to binding constraint and solve for Lagrangian multiplier λ , we get the CES price index as

$$Q = \left[\eta + (1 - \eta)(q + \gamma)^{1-s} \right]^{\frac{1}{1-s}}. \quad (6)$$

Model: Household Problem

[Back](#)

Representative households maximize their lifetime utility by choosing consumption (c), labor supply (n^h), future firm share holding (λ') and future bond holding (ϕ'):

$$\begin{aligned}
 V^h(\lambda, \phi; z_f, \mu) = \max_{c, n^h, \phi', \lambda'} & \left\{ u(c, 1 - n^h) + \beta \sum_{g=1}^{N_z} \pi_{fg}^z V^h(\lambda', \phi'; z'_g, \mu') \right\} \\
 \text{s.t.} \quad & c + q(z_f; \mu)\phi' + \int \rho_1(k', b', \varepsilon'_j, z'_g; \mu') \lambda'(d[k' \times b' \times \epsilon']) , \\
 & \leq w(z_f; \mu)n^h + \phi + \int \rho_0(k, b, \varepsilon_i, z_f; \mu) \lambda(d[k \times b \times \epsilon])
 \end{aligned} \tag{7}$$

where $\rho_0(\cdot)$ is the dividend-inclusive price of the current share, and $\rho_1(\cdot)$ is the ex-dividend price of the future share.

Recursive Equilibrium I

[Back: Overview](#)
[Back: Downward adjusting](#)

A *recursive competitive equilibrium* is a set of function,

$$w, q, q_b, \{d_g\}_{g=1}^{N_z}, \rho_0, \rho_1, v_0, N, K, B, D, I, I_{new}, I_{used}, d, V^h, C^h, N^h, \Phi^h, \Lambda^h \quad (8)$$

such that

- ① v_0 solves (4)-(6), and N is the corresponding policy functions for exiting firms, and (N, K, B, D) are the corresponding policy functions for continuing firms.
- ② V^h solves (7), and (C^h, N^h, Λ^h) are the corresponding policy functions for households.
- ③ $\Lambda^h(k', b', \epsilon'_j, \lambda, \phi; z_f, \mu) = \mu'(k', b', \epsilon'_j; z_f, \mu)$ for all $(k', b', \epsilon_j) \in \mathbf{S}$.

Recursive Equilibrium II

[Back: Overview](#)
[Back: Downward adjusting](#)

4 Labor market clears:

$$N^h(\lambda, \phi; z_f, \mu) = \int_{\mathbf{S}} [N(k, \epsilon_i; z_f, \mu)] \mu(d[k \times b \times \epsilon]), \quad (9)$$

5 For upward-adjusting firms, i.e., firms such that

$v^u(k, b, \epsilon_i, z_f, \mu) \geq v^d(k, b, \epsilon_i, z_f, \mu)$, the policy function

$K(k, b, \epsilon_i, z_f, \mu)$ solves (5), and the investment

$I(k, b, \epsilon_i, z_f, \mu) = K(k, b, \epsilon_i, z_f, \mu) - (1 - \delta)k$. Furthermore, the allocation of $I_{used}(k, b, \epsilon_i, z_f, \mu)$ and $I_{new}(k, b, \epsilon_i, z_f, \mu)$ is (5) and the corresponding aggregate price index is (6).

Recursive Equilibrium III

[Back: Overview](#)
[Back: Downward adjusting](#)

⑥ For downward-adjusting firms, i.e.,

$v^u(k, b, \varepsilon_i, z_f, \mu) < v^d(k, b, \varepsilon_i, z_f, \mu)$, the policy function

$K(k, b, \varepsilon_i, z_f, \mu)$ solves (6), and

$d(k, b, \varepsilon_i, z_f, \mu) = (1 - \delta)k - K(k, b, \varepsilon_i, z_f, \mu)$.

⑦ Good markets clear:

$$\begin{aligned}
 C(z_f, \mu) = \int_{\mathbf{S}} \big\{ & z_f \epsilon_i F(k, N(k, \epsilon_i; z_f, \mu)) \\
 & - (1 - \pi_d) Q(z_f, \mu) I(k, b, \varepsilon_i, z_f, \mu) \\
 & + (1 - \pi_d) q(z_f, \mu) d(k, b, \varepsilon_i, z_f, \mu) \\
 & + \pi_d [q(z_f, \mu)(1 - \delta)k - k_0] \big\} \mu(d[k \times b \times \epsilon])
 \end{aligned}
 , \quad (10)$$

Recursive Equilibrium IV

[Back: Overview](#)
[Back: Downward adjusting](#)

where k_0 is the initial capital stock. We assume k_0 for each entering firm is a fixed χ fraction of the long-run aggregate capital stock, i.e.,

$$k_0 = \chi \int k \tilde{\mu}(d[k \times b \times \epsilon]). \quad (11)$$

- ⑧ The used investment price $q(z_f, \mu)$ clears the market of used capital:

$$\int_{\mathbf{S}} d(k, b, \varepsilon_i, z_f, \mu) \mu(d[k \times b \times \epsilon]) = \int_{\mathbf{S}} i_{used}(k, b, \varepsilon_i, z_f, \mu) \mu(d[k \times b \times \epsilon]). \quad (12)$$

Recursive Equilibrium V

[Back: Overview](#)
[Back: Downward adjusting](#)

9 Evolution of distribution $\Gamma(\mathbf{S}, \mu)$ is defined by

$$\begin{aligned} \mu'(A, \epsilon_i) = & (1 - \pi_d) \int_{\{(k, b, \epsilon_i) | K(k, b, \epsilon_i, z_f; \mu), B(k, b, \epsilon_i, z_f; \mu) \in A\}} \mu(d[k \times b \times \epsilon]) \\ & + \pi_d \chi(k_0) H(\epsilon_j) \end{aligned} \quad (13)$$

where $\chi(k_0) = 1$ if $(k_0, 0) \in A$, and 0 otherwise.

Recursive Equilibrium VI

[Back: Overview](#)[Back: Downward adjusting](#)

10 Bond market clear condition

$$\Phi^h(z_f; \mu) = \int_{\mathbf{s}} B(k, b, \varepsilon, z_f, \mu) \mu(d[k \times b \times \epsilon]) \quad (14)$$

is satisfying Walras's law, where Φ^h is household's policy functions for bond.

Analysis I

[Back](#)

Let $u(c, l) = \log c + \psi l$, and $F(k, n) = k^\alpha n^\nu$, $\alpha + \nu < 1$.

In households' problem, the following three conditions ensure that good market, labor market and bond market clear in this economy:

$$p(z_f; \mu) = D_1 u(c, 1 - n^h) = \frac{1}{c} \quad (15)$$

$$w(z_f; \mu) = \frac{D_2 u(c, 1 - n^h)}{D_1 u(c, 1 - n^h)} = \frac{\psi}{p(z_f; \mu)} \quad (16)$$

$$q_b(z_f; \mu) \equiv \beta \sum_{g=1}^{N_z} \pi_{fg}^z \frac{D_1 u(c_g, 1 - n_g^h)}{D_1 u(c, 1 - n^h)} = \beta \sum_{g=1}^{N_z} \pi_{fg}^z \frac{p(z_g; \mu')}{p(z_f; \mu)}, \quad (17)$$

where $p(z_f; \mu)$ is the output price when firms current dividends is discounted using households' subjective discount factor.

Analysis II

[Back](#)

Following Khan and Thomas (2013), we can rewrite equations (4)-(6) as

$$V_0(k, b, \varepsilon_i; z_f, \mu) = \pi_d \max_n [p(z_f, \mu) x^d(k, b, \varepsilon_i; z_f)] + (1 - \pi_d) V(k, b, \varepsilon_i; z_f, \mu), \quad (18)$$

where

$$V(k, b, \varepsilon_i; z_f, \mu) = \max\{V^u(k, b, \varepsilon_i; z_f, \mu), V^d(k, b, \varepsilon_i; z_f, \mu)\}. \quad (19)$$

The dynamic problem for upward-adjusting firms is

$$\begin{aligned}
 V^u(k, b, \varepsilon_i; z_f, \mu) &= \max_{k', b', D} p(z_f, \mu) D + \beta \sum_{g=1}^{N_z} \sum_{j=1}^{N_\varepsilon} \pi_{fg}^z \pi_{ij}^s V_0(k', b', \varepsilon'_j; z'_g, \mu') \\
 \text{s.t. } 0 \leq D &\leq x^u(k, b, \varepsilon_i; z_f) + q_b b' - Q k' , \\
 x^u(k, b, \varepsilon_i; z_f) &= z_f \varepsilon_i F(k, n) - w(z_f, \mu) n - b + Q(1 - \delta) k \\
 k' &\geq (1 - \delta) k; \quad b' \leq q \zeta k; \quad \mu' = \Gamma(z_f; \mu)
 \end{aligned} \tag{20}$$

and the dynamic problem for downward-adjusting firms is

$$\begin{aligned}
 V^d(k, b, \varepsilon_i; z_f; \mu) &= \max_{k', b', D} p(z_f, \mu) D + \beta \sum_{g=1}^{N_z} \sum_{j=1}^{N_s} \pi_{fg}^z \pi_{ij}^\varepsilon V_0(k', b', \varepsilon'_j; z'_g, \mu') \\
 \text{s.t. } 0 \leq D &\leq x^d(k, b, \varepsilon_i; z_f) + q_b b' - q k' \\
 x^d(k, b, \varepsilon_i; z_f) &= z_f \varepsilon_i F(k, n) - w(z_f, \mu) n - b + q(1 - \delta)k \\
 k' &\leq (1 - \delta)k; \quad b' \leq q \zeta k; \quad \mu' = \Gamma(z_f; \mu)
 \end{aligned} \tag{21}$$

Algorithm Appendix

Bisection on two prices

- Harvey and Stenger (1976) extends bisection method to two dimensions.
- Instead of bisecting on sections on the line, this method bisects on [area of triangles](#).
- The [YouTube video by Oscar Veliz](#) provides a great video explaining the simplified Harvey-Stenger bisection and visualizing the whole process with high aesthetic value. His implementation also hosted on [GitHub](#).
- I solve this model using my own implementation of simplified Harvey-Stenger bisection.

Simplified Harvey-Stenger Bisection: Overview

Harvey and Stenger (1976) algorithm separate into two parts:

- ① generate a polygon that contains the roots, and
- ② bisect on polygon and find triangles containing roots & continue.

My implementation

- simplified 1 by **checking whether the initial triangular area contains roots**. If not, then exit.
- If contains roots, then following 2 and continue bisecting triangles.

Harvey and Stenger (1976) provides a **L test** to detect whether $(0, 0)$ is inside the functional evaluated triangle.

Simplified Harvey-Stenger Bisection: Algorithm I

We find $(x, y) \in \mathbb{R}^2$ such that $f(x, y) = 0$ and $g(x, y) = 0$ for both f and g are continuous function of two variables,

- 1 Take three points $A = (x_1, y_1)$, $B = (x_2, y_2)$, $C = (x_3, y_3)$ to form a triangle $\triangle ABC$ such that line \overline{AB} is the longest.
- 2 Evaluate three points with f and g and form triangle $\triangle A'B'C'$ such that $A' = (f(A), g(A))$ and so on.
- 3 Use **L test** to check whether $(0, 0)$ is inside $\triangle A'B'C'$. If not, back to 1 and start with new $\triangle ABC$.
- 4 Otherwise, find the mid-point D on \overline{AB} and evaluate $D' = (f(D), g(D))$.

Simplified Harvey-Stenger Bisection: Algorithm II

- 5 Find the centroid $E = \frac{A+B+C}{3}$ and linearly interpolate E' with weight $\omega \equiv \frac{\|E-C\|}{\|D-C\|}$ such that $E' = \omega C' + (1 - \omega)D'$, and $\|\cdot\|$ is Euclidean norm.
- 6 Starting iteration on bisecting triangles with stopping criteria $\max\{\|E'\|, \|\overline{AB}\|\} < \varepsilon$.
- 7 Inside loop, use **L test** to check which of the following is true:
 - $(0, 0) \in \triangle A'D'C' \Rightarrow \triangle ADC$ become $\triangle ABC$
 - $(0, 0) \in \triangle B'D'C' \Rightarrow \triangle BDC$ become $\triangle ABC$
 - Neither contains $(0, 0) \Rightarrow$ exit iteration and report failure.

Simplified Harvey-Stenger Bisection: Algorithm III

- ⑧ Rotate $\triangle ABC$ such that \overline{AB} is the longest. Repeat 4 and 5 to get D' and E' .
- ⑨ If $\max\{\|E'\|, \|\overline{AB}\|\} < \varepsilon$, then stop and report $E = (x_E, y_E)$ as solution. Otherwise, repeat 6, 7 and 8.

Simplified Harvey-Stenger Bisection: L function

Let A, B , and V be three points $(x_i, y_i), i \in \{A, B, V\}$. Define

$$L(A, B, V) = (y_B - y_A)(x_V - x_A) - (x_B - x_A)(y_V - y_A). \quad (22)$$

If $L(A, B, V) = 0$, then it means V is on the line \overline{AB} :

$$L(A, B, V) = 0$$

$$(y_B - y_A)(x_V - x_A) = (x_B - x_A)(y_V - y_A)$$

$$\frac{y_V - y_A}{x_V - x_A} = \frac{y_B - y_A}{x_B - x_A}$$

If $L(A, B, V)$ is nonzero, then V is either on the right-hand side or left-hand side of \overline{AB} , depends on whether V is in between \overline{AB} or outside.

Simplified Harvey-Stenger Bisection: L test

The sufficient condition to detect whether $V = (0, 0)$ is inside $\triangle ABC$ is

$$L(A, B, V)L(A, B, C) \geq 0$$

$$\&\& \quad L(B, C, V)L(B, C, A) \geq 0$$

$$\&\& \quad L(C, A, V)L(C, A, B) \geq 0$$

where $L(A, B, V)L(A, B, C)$ means that point V and the other point C are on the same side of line \overline{AB} .

The requirement for all three conditions to hold ensures that V always on the same side as the third point, which means V is inside $\triangle ABC$.

Frequency and Functional Form [Back](#)

- Model frequency: annual
- HH utility function: $u(c, l) = \log c + \varphi l$
- Production function: $z\varepsilon F(k, n) = z\varepsilon k^\alpha n^\nu$
- Initial capital for normal entrant: $k_0 = \chi \int k \tilde{\mu}(d[k \times b \times \varepsilon])$
- Initial bond holding for normal entrant: $b_0 = 0$
- Idiosyncratic productivity shock: $\log \varepsilon' = \rho_\varepsilon \log \varepsilon + \eta'_\varepsilon$
 - 7-state Markov chain discretized from Rowenhorst algorithm
