

# Aggregate Implications of Corporate Taxation over the Business Cycle

Hui-Jun Chen

The Ohio State University

Job Market Paper

[\[Click here for the latest version\]](#)

January 2025

# Outline

- Introduction
- Model
- Calibration
- Long-run effects of corporate tax deductions
- Short-run dynamics of corporate tax deduction
- Application: policy evaluation

# What are the macro effects of corporate tax deductions?

- Fact** large deductions (100-150B), investment responses are large and heterogeneous  
(The Joint Committee on Taxation (2017), Chodorow-Reich, Zidar and Zwick (2024b), Zwick and Mahon (2017), Ohn (2018, 2019))
- Model** hetero. firms + financial frictions + corporate taxes + investment deduction
- Validation** (i) deduction policies in matching investment rate distribution (Cooper and Haltiwanger (2006))  
(ii) qualitative pattern of hetero. investment response to policy (Zwick and Mahon (2017))
- Application** GE effects on investment deductions as counter-cyclical policies
- against different shocks (TFP v.s. credit); v.s. other stimulus policies (TCJA)

## Two policies that accelerates investment deductions

- Firms' taxable income is deductible by eligible investment that follows deduction schedule
- **Section 179 expensing**: allow firms' inv. lower than a threshold to deduct entire cost
- **Bonus depreciation**: allow all firms to deduct a bonus fraction, the rest is carried forward

## Preview of findings

- Long run** Comparing steady states with policy expansion; cost: 0.3% of GDP
- **Targeted** policy boosts GDP by 1.6%, yet **untargeted** one boosts by 1.06%
  - Convex combination of both deductions only boosts GDP by 1.3% (Ohrn (2019))
- Response** Comparing two economy, with and without investment tax deductions,
- Deductions reduce half life of output responses by 2 years after credit shocks
  - Deductions have almost no effect after TFP shocks
- One-period** Comparing temporarily raise deductions after a credit shock,
- Targeted policy boost GDP by 0.51%
  - Untargeted policy only boost GDP by 0.38%

# Key mechanisms

Recall **two inefficiencies**: **financial frictions** and **tax wedges**

- Financial frictions hinder capital accumulation of small firms by limit investment loan
- Wedges on shadow prices of capital  $\Rightarrow$  results in firms not investing (inaction)

Role of the deduction policies: lower user cost of capital and decrease needs for funding

Who gets the tax credit matters:

- large firms raise **dividend**; small firms raise **investment**
- Target policies motivate **high-productivity firms** to invest more

# Literature

- Large empirical literature on responsiveness of investment to tax credit
  - Public firm data: Goolsbee (1998), Cummins, Hassett and Hubbard (1996), House and Shapiro (2008), Lamont (1997); Firm/State-level data: Zwick and Mahon (2017), Ohrn (2018), Ohrn (2019)

New - evaluates aggregate effects of both investment subsidy policies

- Representative firm model on the response of fiscal policies with simplistic tax structure
  - Hall and Jorgenson (1967), Summers, Bosworth, Tobin and White (1981), Fernández-Villaverde (2010), Occhino (2022), Occhino (2023), Chodorow-Reich, Smith, Zidar and Zwick (2024a)

New - accounts for distributional effects and a realistic tax deduction structure

- Heterogeneous firm model that accounts for distribution effects of shocks
  - Khan and Thomas (2013), House (2014), Koby and Wolf (2020), Winberry (2021)

New - utilize the technique and expands the analysis to counter-cyclical fiscal policies

# Outline

- Introduction
- **Model**
- Calibration
- Long-run effects of corporate tax deductions
- Short-run dynamics of corporate tax deduction
- Application: policy evaluation

# Environment

**Household:** supplies labor, pays labor tax, lends risk-free loans, and owns the firms

**Government:** collect taxes to fund exogenous government spending

**Firms:** states  $(k, b, \psi, \varepsilon)$

- Deductible stock  $\psi$  carry unrealized investment tax deductions forward to the next period
- DRS production; persistent idiosyncratic productivity  $\varepsilon$ ; i.i.d. exit shock  $\pi_d$
- Capital  $k$  accumulation is hindered by financial frictions and tax wedges:
  - ① collateral constraint  $b' \leq \theta k'$
  - ② selling capital generate taxable income  $\Rightarrow$  higher corporate tax burden

# Investment deductions and taxable income

$$\mathcal{I}(k', k, \psi, \varepsilon) = \max \left\{ z\varepsilon f(k, n) - wn - \mathcal{J}(k', k)(k' - (1 - \delta)k) - \delta^\psi \psi, 0 \right\},$$

- Gov won't issue tax rebate when taxable income is negative  $\Rightarrow$  **zero lower bound**
- $\mathcal{J}(k', k)$ : indicator function for investment deduction policies

$$\mathcal{J}(k', k) = \begin{cases} \omega & \text{if } k' - (1 - \delta)k \leq \bar{I} \\ \xi\omega & \text{if } k' - (1 - \delta)k > \bar{I} \end{cases}$$

- $\bar{I}$ : Section 179 threshold (targeted policy)
- $\xi \in [0, 1]$ : bonus depreciation (untargeted policy)
- $\omega$ : fraction of eligible investment to total investment

# Deductible stock to capture IRS deduction schedule

$$\mathcal{I}(k', k, \psi, \varepsilon) = \max \left\{ z\varepsilon f(k, n) - wn - \mathcal{J}(k', k)(k' - (1 - \delta)k) - \delta^\psi \psi, 0 \right\},$$

- Deductible stock  $\psi$  follows law of motion,

$$\psi' = (1 - \delta^\psi)\psi + (\omega - \mathcal{J}(k', k))(k' - (1 - \delta)k)$$

- $(\omega - \mathcal{J}(k', k))(k' - (1 - \delta)k)$ : investment deduction that is not realized immediately
- $\delta^\psi > \delta$ : captures the favorable treatment for deduction (“accelerated depreciation”)

# How corporate tax burden affect budget

$$D = z\varepsilon F(k, n) - wn - b + qb' - (k' - (1 - \delta)k) - \tau^c \mathcal{I}(k', k, \psi, \varepsilon)$$

If  $\mathcal{I}(k', k, \psi, \varepsilon) > 0$ ,

(Barro and Furman (2018), Chodorow-Reich, Smith, Zidar and Zwick (2024a))

$$D = \underbrace{(1 - \tau^c)}_{\text{taxed}} (z\varepsilon F(k, n) - wn) - b + qb' - \underbrace{(1 - \tau^c \mathcal{J}(k', k))}_{\text{deduction}} (k' - (1 - \delta)k) + \tau^c \delta^\psi \psi$$

More generous deduction policies ( $\mathcal{J}(k', k) \uparrow$ ), higher dividend payment

If  $\mathcal{I}(k', k, \psi, \varepsilon) \leq 0$ ,

$$D = z\varepsilon F(k, n) - wn - b + qb' - (k' - (1 - \delta)k)$$

# How two kinks dissect choice spaces

# Distortion created by tax wedge

$D = (z\varepsilon F(k, n) - wn) - b + qb' - I$   
 capital decision rule at median productivity with zero debt and taxable capital

# Distortion created by tax wedge

$$D = (1 - \tau^c)(z\varepsilon F(k, n) - wn) - b + qb' -$$

$$I \mid_{I \geq 0} - (1 - \tau^c \omega) I \mid_{I < 0}$$

capital decision rule at median productivity with zero debt and taxable capital

# Distortion created by tax wedge

$$D = (1 - \tau^c)(z\varepsilon F(k, n) - wn) - b + qb' - (1 - \tau^c \mathcal{J}(k', k))I \mid_{I \geq 0} - (1 - \tau^c \omega)I \mid_{I < 0} + \tau^c \delta^\psi \psi$$

capital decision rule at median productivity with zero debt and taxable capital

# Distortion created by tax wedge

$$D = (1 - \tau^c)(z\varepsilon F(k, n) - wn) - b + qb' - (1 - \tau^c \mathcal{J}(k', k))I \mid_{I \geq 0} - (1 - \tau^c \omega)I \mid_{I < 0} + \tau^c \delta^\psi \psi$$

capital decision rule at median productivity with zero debt and taxable capital

# Value function and discrete choices

$$D(k', b', k, b, \psi, \varepsilon) = z\varepsilon F(k, n) - wn - b + qb' - (k' - (1 - \delta)k) - \tau^c \mathcal{I}(k', k, \psi, \varepsilon)$$

$$v^0(k, b, \psi, \varepsilon; \mu) = \pi_d \max_n \left\{ D(0, 0, k, b, \psi, \varepsilon) \right\} + (1 - \pi_d) v(k, b, \psi, \varepsilon; \mu)$$

$$v(k, b, \psi, \varepsilon; \mu) = \max \left\{ v^H(k, b, \psi, \varepsilon; \mu), v^L(k, b, \psi, \varepsilon; \mu), v^N(k, b, \psi, \varepsilon; \mu) \right\}$$

For each option, firms maximize dividend and continuation value subject to

(1) budget constraints, (2) collateral constraints, and (3) deductible stock LoM

# Outline

$\xi = 0.5$	2015 bonus rate		
$\bar{I} = 0.092$	2015 threshold model counterpart	<a href="#">Detail</a>	

# Model validation: investment rate distribution for large firms

- Simulate 50,000 **unconstrained** firms for 100 periods
- Take the last 17 periods and plot investment rate distribution for firm  $\times$  periods
- Model with investment deduction tightly match the investment rate distribution

# Model validation: heterogeneous investment response in the short-run

- Simulate 50,000 firms for 100 periods
- Drop credit parameter  $\theta$  by 27% at date 79 and boost bonus rate at date 80
- aggregate tax term elasticity from date 79 to date 80:  $-1.23$
- Zwick and Mahon (2017):  $-1.6$

# Outline

- Introduction
- Model
- Calibration
- Long-run effects of corporate tax deductions
- Short-run dynamics of corporate tax deduction
- Application: policy evaluation

## Aggregate outcomes as percentage deviation of baseline

Variable	S179	Bonus	S179 + Bonus	Tax cut
Output	1.61%	1.06%	1.31%	0.64%
Consumption	1.55%	0.92%	1.27%	0.56%
Labor	0.06%	0.13%	0.04%	0.08%
Capital	4.22%	3.21%	3.39%	1.95%
Investment	4.22%	3.21%	3.39%	1.95%
Measured TFP	0.32%	0.03%	0.28%	0.01%
Dividend	2.08%	10.14%	2.99%	-2.09%

- Each policy costs 0.3% of baseline GDP and delivers the same government spending  $\bar{G}$
- In S179 + Bonus, policy tools are 82% of the level in S179 and Bonus
- Untargeted nature of bonus induces **dividend payment**: recall  $D \propto \mathcal{J}(k', k)$ 
  - unconstrained firms: user cost of capital drops, easier to achieve target capital

# Distribution of Excess Return on Investment

	mean	mass at 0
baseline	1.24	20%
S179	1.08	31%
Bonus	1.09	26%

# Expanding S179 reduces investment wedge for productive firms

efficiency low excess return

S179 high  $\varepsilon$  firms: (+)

low  $\varepsilon$  firms: (-)

Bonus all firms (+)

low  $\varepsilon$  firms: (++)

# Conclusions

- Equilibrium model of how investment tax credit and subsidy policies boost economy
- Use model to quantify the macroeconomics effects of both subsidy policies:
  - S179 boost GDP by motivating marginal firms to be unconstrained and alleviate misallocation
  - Bonus depreciation is 30% less effective than S179 as it motivates dividend payment
  - Cutting statutory tax rate is the least effective
- What's next:
  - Permanent change in policies
  - Policy effectiveness under aggregate uncertainty
  - Endogenizing financial frictions: does deduction policy reduce the incidence of firm default?

- Empirical Literatures
- Model Appendix

# Corporate tax deductions in the US

- Consider a firm buying \$1000 of computer and interest rate is 4%:

Year	Cost $\times$ Depreciation %	Normal		50% Bonus	S179 eligible / 100% Bonus
0	$\$1000 \times 20.00\%$	\$200	$\Rightarrow +800 \times 0.5$	\$600	\$1000
1	$\$1000 \times 32.00\%$	\$320		\$160	\$0
2	$\$1000 \times 19.20\%$	\$192		\$96	\$0
3	$\$1000 \times 11.52\%$	\$115.2	$\Rightarrow \times 0.5$	\$57.5	\$0
4	$\$1000 \times 11.52\%$	\$115.2		\$57.5	\$0
5	$\$1000 \times 5.76\%$	\$57.6		\$29	\$0
Total		\$1000		\$1000	\$1000
NPV		\$933		\$966	\$1000

## Example: Modified Accelerated Cost Recovery System (MARCS)

Shawn bought and placed in service a used pickup for \$15,000 on March 5, 1998. The pickup has a 5 year class life. His depreciation deduction for each year is computed in the following table.

Year	Cost $\times$ MACRS %	Depreciation
1998	\$15,000 $\times$ 20.00%	\$3,000
1999	\$15,000 $\times$ 32.00%	\$4,800
2000	\$15,000 $\times$ 19.20%	\$2,880
2001	\$15,000 $\times$ 11.52%	\$2,880
2002	\$15,000 $\times$ 11.52%	\$2,880
2003	\$15,000 $\times$ 5.76%	\$864
Total		\$15,000

MACRS Percentage Table

Year	3 Year	5 Year	7 Year
1	33.33%	20.00%	14.29%
2	44.45%	32.00%	24.49%
3	14.81%	19.20%	17.49%
4	7.41%	11.52%	12.49%
5		11.52%	8.93%
6		5.76%	8.92%
7			8.93%
8			4.46%

# Long-duration industries respond more to bonus depreciation

Panel A. Intensive margin: bonus I

Panel B. Intensive margin: bonus II

Panel C. Extensive margin: bonus I

Panel D. Extensive margin: bonus II

--- Treatment group (long duration industries)  
--- Control group (short duration industries)

# Conforming states enjoys 18% of investment boosts

**Table:** Investment Impacts of State Bonus and State 179

Dependent Var:	Ln CapEx			
Specification	(1)	(2)	(3)	(4)

# Heterogeneous response to bonus depreciation

## How to determine $\bar{I}$

In 2015,

- Real investment: \$2459.8B (Table 3.7 BEA)
- Numbers of firms in US: 5,900,731 (SUSB)
- Average investment: \$416,853
- Section 179 deduction: \$500,000
- Choose  $\bar{I} = \frac{500,000}{416,853} \times \text{aggregate investment} \sim 0.092$

## Unconstrained firms' problem: positive taxable income

Let  $W$  function be the value function for unconstrained firms.

The start-of-period value before the realization of exit shock is

$$W^0(k, b, \psi, \varepsilon; \mu) = p(\mu)\pi_d \max_n \left\{ z\varepsilon F(k, n) - wn - b + (1 - \delta)k - \tau^c \mathcal{I}(0, k, \psi) \right\} \\ + (1 - \pi_d)W(k, b, \psi, \varepsilon; \mu)$$

Upon survival, unconstrained firms undertake binary choice,

$$W(k, b, \psi, \varepsilon; \mu) = \max \left\{ W^L(k, b, \psi, \varepsilon; \mu), W^H(k, b, \psi, \varepsilon; \mu), W^N(k, b, \psi, \varepsilon; \mu) \right\}.$$

Firm's current value:  $W(k, b, \psi, \varepsilon; \mu) = W(k, 0, \psi, \varepsilon; \mu) - pb$

Start-of-period value:  $W^0(k, b, \psi, \varepsilon; \mu) = W^0(k, 0, \psi, \varepsilon; \mu) - pb.$

## Unconstrained firms' problem (Cont.)

Given these transformation, firms' problem can be rewritten as

$$\begin{aligned}
 W^L(k, b, \psi, \varepsilon_i; \mu) &= p \left( (1 - \tau^c)(z\varepsilon f(k, n) - wn) - b + (1 - \tau^c\omega)(1 - \delta)k + \tau^c\delta^\psi\psi \right) \\
 &\quad + \max_{k' \leq (1-\delta)k + \bar{I}} \left\{ -p(1 - \tau^c\omega)k' + \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon W^0(k', 0, \psi', \varepsilon_j; \mu') \right\}, \\
 W^H(k, b, \psi, \varepsilon_i; \mu) &= p \left( (1 - \tau^c)(z\varepsilon f(k, n) - wn) - b + (1 - \tau^c\omega\xi)(1 - \delta)k + \tau^c\delta^\psi\psi \right) \\
 &\quad + \max_{k' \in ((1-\delta)k + \bar{I}, \bar{k})} \left\{ -p(1 - \tau^c\omega\xi)k' + \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon W^0(k', 0, \psi', \varepsilon_j; \mu') \right\}, \\
 W^N(k, b, \psi, \varepsilon_i; \mu) &= p(z\varepsilon f(k, n) - wn - b + (1 - \delta)k) \\
 &\quad + \max_{k' \geq \bar{k}} \left\{ -pk' + \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon W^0(k', 0, \psi', \varepsilon_j; \mu') \right\},
 \end{aligned}$$

## Unconstrained firms' problem when taxable income is nonpositive

The following question defines the lower bound for capital when the firms are having zero or negative taxable income:

$$W^N(k, b, \psi, \varepsilon_i; \mu) = p(y - wn - b + (1 - \delta)k) + \max_{k'} \left\{ -pk' + \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon W^0(k', 0, \psi', \varepsilon_j; \mu') \right\},$$

where

$$\begin{aligned} \psi' &= (1 - \delta^\psi)\psi + (1 - \mathcal{J}(I))\omega I && \text{if } (y - wn - \mathcal{J}(I)\omega I - \delta^\psi\psi) \geq 0 \\ \psi' &= \psi + \omega I - y + wn && \text{if } (y - wn - \mathcal{J}(I)\omega I - \delta^\psi\psi) < 0 \end{aligned}$$

## Minimum Saving Policy

The *minimum saving policy*,  $B^w(k, \psi, \varepsilon)$ , can be recursively calculated by the following two equations with both policy functions for labor,  $N(k, \varepsilon)$ , and capital,  $K^w(k, \psi, \varepsilon)$ ,

$$B^w(k, \psi, \varepsilon) = \min_{\varepsilon_j} \left( \tilde{B}(K^w(k, \psi, \varepsilon_i), \psi', \varepsilon_j) \right)$$

$$\tilde{B}(k, \psi, \varepsilon_i) = \frac{1}{1 - \tau^c \tau^b} \left( (1 - \tau^c) \pi(k, \varepsilon_i) + \tau^c \delta^\psi \psi \right. \\ \left. - (1 - \tau^c \omega \mathcal{J}(K^w(k, \psi, \varepsilon_i) - (1 - \delta)k)) (K^w(k, \psi, \varepsilon_i) - (1 - \delta)k) \right. \\ \left. + q \min \{ B^w(k, \psi, \varepsilon_i), \theta K^w(k, \psi, \varepsilon_i) \} \right),$$

I set interest deductability  $\tau^b = 0$  as minimum saving policy cannot converge with positive  $\tau^b$ . As  $\frac{1}{q}$  is the risk-free rate, firms are paying  $\frac{q}{1 - \tau^c \tau^b} > q$ , implies the interest rate that firms are paying is less than risk-free rate.

## Constrained firms' problem

Constrained firms' bond decision is implied by binding collateral constraints, i.e.,  $B^c(k, b, \psi, \varepsilon) = \theta K^c(k, b, \psi, \varepsilon)$ , and the capital decision  $K^c(k, b, \psi, \varepsilon)$  has to be determined recursively.

$$J(k, b, \psi, \varepsilon; \mu) = \max \left\{ J^H(k, b, \psi, \varepsilon; \mu), J^L(k, b, \psi, \varepsilon; \mu), J^N(k, b, \psi, \varepsilon; \mu) \right\},$$

and  $J^H$ ,  $J^L$  and  $J^N$  are defined as

## Constrained firms' problem: invest higher than threshold

$$J^H(k, b, \psi, \varepsilon; \mu) = \max_{k' \in \Omega_H(k, b, \psi, \varepsilon)} \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon V^0(k', b_H^2(k'), \psi', \varepsilon_j; \mu'),$$

subject to

$$b_H(k') = -\frac{1}{q} \left( (1 - \tau^c) \pi(k, \varepsilon) - b + \tau^c \delta^\psi \psi - (1 - \tau^c \omega \xi) (k' - (1 - \delta)k) \right),$$

$$\psi' = (1 - \delta^\psi) \psi + (1 - \xi) (k' - (1 - \delta)k),$$

The choice sets for  $H$ -type firms' problem are defined by

$$\Omega_H(k, b, \psi, \varepsilon) = \left[ \max \left\{ (1 - \delta)k + \bar{I}, \min \left\{ \bar{k}_H(k, b, \psi, \varepsilon), \bar{k} \right\} \right\}, \min \left\{ \bar{k}_H(k, b, \psi, \varepsilon), \bar{k} \right\} \right],$$

Maximum affordable capital:  $\bar{k}_H = \frac{(1 - \tau^c) \pi(k, \varepsilon) + \tau^c \delta^\psi \psi - b + (1 - \tau^c \omega \xi) (1 - \delta)k}{1 - \tau^c \omega \xi - q\theta}$

# Constrained firms' problem: invest lower than threshold

$$J^L(k, b, \psi, \varepsilon; \mu) = \max_{k' \in \Omega_L(k, b, \psi, \varepsilon)} \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon V^0(k', b_L^2(k'), \psi', \varepsilon_j; \mu'),$$

subject to

$$b_L(k') = \frac{1}{q} \left( - (1 - \tau^c) \pi(k, \varepsilon) + b - \tau^c \delta^\psi \psi + (1 - \tau^c \omega)(k' - (1 - \delta)k) \right),$$

$$\psi' = (1 - \delta^\psi) \psi.$$

Choice set:  $\Omega_L(k, b, \psi, \varepsilon) = \left[ 0, \max \left\{ 0, \min \left\{ (1 - \delta)k + \bar{I}, \bar{k}_L(k, b, \psi, \varepsilon) \right\} \right\} \right],$

Maximum affordable capital:  $\bar{k}_L = \frac{(1 - \tau^c) \pi(k, \varepsilon) + \tau^c \delta^\psi \psi - b + (1 - \tau^c \omega)(1 - \delta)k}{1 - \tau^c \omega - q\theta}.$

# When taxable income is negative for constrained firms

$$J^N(k, b, \psi, \varepsilon; \mu) = \max_{k' \in \Omega^N(k, b)} \beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon V^0(k', b_N(k'), \psi', \varepsilon_j; \mu')$$

subject to

$$b_N(k') = -\frac{1}{q} (z\varepsilon f(k, n) - wn - b - (k' - (1 - \delta)k))$$

$$\psi' = (1 - \delta^\psi)\psi + (1 - \xi)\omega(k' - (1 - \delta)k)$$

$$\Omega^N(k, b, \varepsilon) = \left[ \min \left\{ \max \left\{ \bar{k}, 0 \right\}, \bar{k}_N(k, b, \varepsilon) \right\}, \bar{k}_N(k, b, \varepsilon) \right]$$

$$\bar{k}_N(k, b, \varepsilon) = \frac{z\varepsilon f(k, n) - wn - b + (1 - \delta)k}{1 - q\theta}$$

## When taxable income is nonpositive

- In principle, IRS will not give tax subsidy if taxable income is negative.
- User cost of capital for firms with nonpositive taxable income is not affected by deduction.
- Solving for  $\mathcal{I} \geq 0$  gives the upper threshold for capital decision that pays corporate tax:

$$k' \leq \bar{k} \equiv \min \left( \frac{z\varepsilon f(k, n) - wn - \delta^\psi \psi}{\xi\omega} + (1 - \delta)k, \mathbf{K}_{max} \right),$$

Assume  $F(k, n) = k^\alpha n^\nu$ , I solve for  $\bar{k} = (1 - \delta)k + \bar{I}$  and get,

$$\tilde{k} \equiv \left( \frac{\delta^\psi \psi + \xi\omega \bar{I}}{A(w) z^{\frac{1}{1-\nu}} \varepsilon^{\frac{1}{1-\nu}}} \right)^{\frac{1-\nu}{\alpha}}$$

# Firms that invest higher than threshold

$$v^H(k, b, \psi, \varepsilon_i; \mu) = \max_{D, k', b', n} D + \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon Q(\mu) v^0(k', b', \psi', \varepsilon_j; \mu'),$$

subject to

$$0 \leq D = (1 - \tau^c)(z\varepsilon F(k, n) - wn) - b + qb' - (1 - \tau^c \xi \omega)(k' - (1 - \delta)k) + \tau^c \delta^\psi \psi. \quad (\text{Dividend})$$

$$k' \in ((1 - \delta)k + \bar{I}, \bar{k}) \text{ and } k > \tilde{k} \quad (\text{Choice Sets})$$

$$b' \leq \theta k' \quad (\text{Collateral})$$

$$\psi' = (1 - \delta^\psi)\psi + (\omega - \omega \xi)(k' - (1 - \delta)k) \quad (\text{deductible stock LoM})$$

$$\mu' = \Gamma(\mu) \quad (\text{Distribution LoM})$$

# Firms that invest lower than threshold

$$v^L(k, b, \psi, \varepsilon_i; \mu) = \max_{D, k', b', n} D + \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon Q(\mu) v^0(k', b', \psi', \varepsilon_j; \mu'), \quad (1)$$

subject to

$$0 \leq D = (1 - \tau^c)(z\varepsilon F(k, n) - wn) - b + qb' - (1 - \tau^c\omega)(k' - (1 - \delta)k) + \tau^c\delta^\psi\psi. \quad (\text{Dividend})$$

$$k' \leq (1 - \delta)k + \bar{I} \text{ and } k > \hat{k} \quad (\text{Choice Sets})$$

$$b' \leq \theta k' \quad (\text{Collateral})$$

$$\psi' = (1 - \delta^\psi)\psi \quad (\text{Tax Benefit LoM})$$

$$\mu' = \Gamma(\mu) \quad (\text{Distribution LoM})$$

# Firms not paying corporate tax

$$v^N(k, b, \psi, \varepsilon_i; \mu) = \max_{D, k', b', n} D + \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon Q(\mu) v^0(k', b', \psi', \varepsilon_j; \mu'), \quad (2)$$

subject to

$$0 \leq D = z\varepsilon F(k, n) - wn - b + qb' - (k' - (1 - \delta)k) \quad (\text{Dividend})$$

$$k' \geq \max(\bar{k}, 0) \quad (\text{Choice Sets})$$

$$b' \leq \theta k' \quad (\text{Collateral})$$

$$\psi' = (1 - \delta^\psi)\psi + (\omega - \mathcal{J}(k', k))(k' - (1 - \delta)k) \quad (\text{Tax Benefit LoM})$$

$$\mu' = \Gamma(\mu) \quad (\text{Distribution LoM})$$

# Household

In each period, representative households maximize their lifetime utility by choosing consumption,  $c$ , labor supply,  $n^h$ , future firm shareholding,  $\lambda'$ , and future bond holding,  $a'$ :

$$V^h(\lambda, a; \mu) = \max_{c, n^h, a', \lambda'} \left\{ u(c, 1 - n^h) + \beta V^h(\lambda', a'; \mu') \right\}$$

$$\text{s.t.} \quad c + q(\mu)a' + \int \rho_1(k', b', \psi', \varepsilon'; \mu) \lambda' (d[k' \times b' \times \psi' \times \varepsilon']) \leq (1 - \tau^n) w(\mu) n^h, \quad (3)$$

$$+ a + \int \rho_0(k, b, \psi, \varepsilon; \mu) \lambda (d[k \times b \times \psi \times \varepsilon]) + R - T$$

where  $\rho_0(k, b, \psi, \varepsilon)$  is the dividend-inclusive price of the current share,  $\rho_1(k', b', \psi', \varepsilon')$  is the ex-dividend price of the future share,  $\tau^n$  is payroll tax,  $R$  is the steady state government lump-sum rebates to households, and  $T$  is lump-sum tax to fund policy changes.

# Equilibrium

Market clear :  $Y = C + [(1 - \pi_d)(K' - (1 - \delta)K) - \pi_d(1 - \delta)K] + \pi_d k_0 + \bar{G}$

Output :  $Y = \int z\varepsilon F(k, n(k, \varepsilon))d\mu$

Capital :  $K = \int k d\mu$

Labor :  $N^h = N$ , where  $N = \int n(k, \varepsilon)d\mu$

Deductible stocks :  $\Psi = \int \psi(k, \psi, \varepsilon)d\mu$

Debt :  $B = \int b d\mu$

Corp. revenue :  $R = \tau^c \int \max(z\varepsilon F(k, n) - wn - \mathcal{J}(k', k)(K' - (1 - \delta)k) - \delta^\psi \psi, 0) d\mu$

Gov. Budget :  $\bar{G} = \tau^n w N^h + R + T$

# Household Optimality Conditions

- After-tax wage fully compensate MRS between leisure and consumption:

$$w(\mu) = \frac{1}{(1 - \tau^n)} \frac{D_2 u(c, 1 - n^h)}{D_1 u(c, 1 - n^h)}$$

With  $u(c, 1 - n^h) = \log c + \varphi(1 - n^h)$ , implied Frisch elasticity is  $\infty$ ,

$$w(\mu) = \frac{\varphi c}{(1 - \tau^n)}$$

- As there's no agg. shock, SDF equals discounting factor equals to bond prices

$$Q(\mu) = \beta \frac{D_1 u(c, 1 - n^h)}{D_1 u(c, 1 - n^h)} = \beta = q$$

# Exogenous Parameters

	Parameter	Value	Reason
<i>Exogenous parameters</i>			
fraction of entrants capital endowment	$\chi$	0.1	10% of aggregate capital
exogenous exit rate	$\pi_d$	0.1	10% entry and exit
Corporate tax rate	$\tau^c$	0.21	US Tax schedule after TCJA
Deductible stock depreciation rate	$\delta^\psi$	0.138	$\delta^\psi = 2\delta$ (Double-declining balance)

# Frequency and Functional Form

- Model frequency: annual
- Household utility function:  $u(c, n^h) = \log c + \varphi(1 - n^h)$
- Production function:  $F(k, n) = k^\alpha n^\nu$
- Initial capital for entrants:  $k_0 = \chi \int k \tilde{\mu}(d[k \times b \times \psi \times \varepsilon])$
- Initial bond and taxable capital:  $b_0 = 0$  and  $\psi_0 = 0$
- Idiosyncratic productivity shock:  $\log \varepsilon' = \rho_\varepsilon \log \varepsilon + \eta'_\varepsilon$ ,  $\eta_\varepsilon \sim N(0, \sigma_\varepsilon^2)$ 
  - 7-state Markov chain discretized using Tauchen algorithm

*N*-type firms:

$$\beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon \left[ \frac{\partial V^0(k', b', \psi', \varepsilon_j; \mu)}{\partial k'} + \frac{\partial V^0(k', b', \psi', \varepsilon_j; \mu)}{\partial \psi'} \frac{\partial \psi'}{\partial k'} \right] - 1$$

*H*-type firms:

$$\beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon \left[ \frac{\partial V^0(k', b', \psi', \varepsilon_j; \mu)}{\partial k'} + \frac{\partial V^0(k', b', \psi', \varepsilon_j; \mu)}{\partial \psi'} \frac{\partial \psi'}{\partial k'} \right] - (1 - \tau^c \omega \xi)$$

*L*-type firms:

$$\beta \sum_{j=1}^{N_\varepsilon} \pi_{ij}^\varepsilon \left[ \frac{\partial V^0(k', b', \psi', \varepsilon_j; \mu)}{\partial k'} + \frac{\partial V^0(k', b', \psi', \varepsilon_j; \mu)}{\partial \psi'} \frac{\partial \psi'}{\partial k'} \right] - (1 - \tau^c \omega)$$

## Approximating the derivatives of the value functions

I use RHS and LHS secant to approximate the derivatives of the value functions.

Let  $i_\varepsilon = 1, \dots, N(\varepsilon)$ ,  $i_b = 1, \dots, N(b)$ ,  $i_k = 1, \dots, N(k)$  and  $i_\psi = 1, \dots, N(\psi)$ .

RHS secant at  $(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})$ ,  $i_k = 1, \dots, N(k) - 1$  is

$$s_r(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) = \frac{V^0(k_{i_k+1}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) - V^0(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})}{k_{i_k+1} - k_{i_k}}$$

LHS secant at  $(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})$ ,  $i_k = 2, \dots, N(k)$  is

$$s_l(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) = \frac{V^0(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) - V^0(k_{i_k-1}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})}{k_{i_k} - k_{i_k-1}}$$

# Approximating the derivatives of the value functions (Cont.)

When  $i_k = 2, \dots, N(k) - 1$ ,

$$D_k V^0(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) = 0.5 s_r(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) + 0.5 s_l(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})$$

When  $i_k = 1$ ,

$$D_k V^0(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) = s_r(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})$$

When  $i_k = N(k)$ ,

$$D_k V^0(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon}) = s_l(k_{i_k}, b_{i_b}, \psi_{i_\psi}, \varepsilon_{i_\varepsilon})$$
